

ABSTRACT OF THE DISCLOSURE

A process for creating displayable imprints includes the steps of first adding water to a flexible container housing desiccated molding material, and mixing the water and molding material. The molding material is then poured into a mold which is configured to create a window. A predetermined object, such as a child's hands or feet, or a pet's paw, is imprinted in the molding material. The molding material is allowed to set, and a photograph is associated with the window by placing the photograph into a clear plastic insert having opposite faces which capture the photograph, and attaching the insert to the set molding material such that the photograph can be viewed through the window. The finished product can be displayed on an easel.
